# **Operating System Project 6**

### Project goal:

Designing a Virtual Memory Manager

- This project consists of writing a program that translates logical to 16 physical addresses for a virtual address space of size 2<sup>16</sup> =65536 bytes.
- Your program will read from a file containing logical addresses and, using a TLB as well as a page table, will translate each logical address to its corresponding physical address and output the value of the byte stored at the translated physical address.
- The goal of this project is to simulate the steps involved in translating logical to physical addresses.

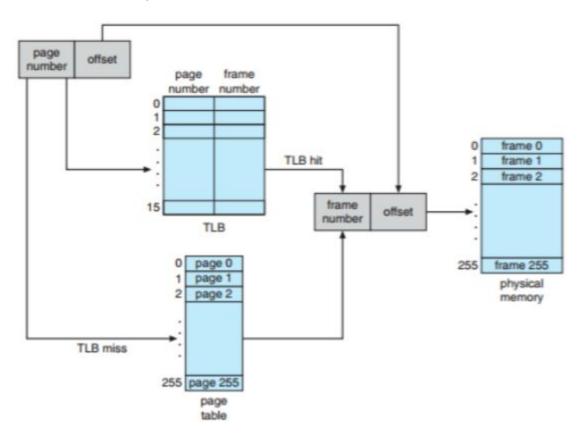

## Specifics:

- Your program will read a file containing several 32-bit integer numbers that represent logical addresses. However, you need only be concerned with 16-bit addresses.
  - These 16 bits are divided into :
    - 8-bit page number
    - 8-bit page offset.

- Other specifics include the following :
  - o 28 entries in the page table
  - Page size of 2<sup>8</sup> bytes
  - 16 entries in the TLB(Use FIFO replacement)
  - Frame size of 28 bytes

- 256 frames
- Physical memory of 65536 bytes(256 frames \* 256-byte frame size)
- Address-translation process

# Handling Page Faults:

- The backing store is represented by the file BACKING\_STORE.bin, a binary file of size 65,536 bytes.
- When a page fault occurs, you will read in a 256-byte page from the file BACKING\_STORE and store it in an available page frame in physical memory.
- For example :
  - If a logical address with page number 15 resulted in a page fault, your program would read in page 15 from BACKING\_STORE (remember that pages begin at 0 and are 256 bytes in size) and store it in a page frame in physical memory.

- Once this frame is stored (and the page table and TLB are updated), subsequent accesses to page 15 will be resolved by either the TLB or the page table.
- You will need to treat BACKING\_STORE.bin as a random-access file so that
  you can randomly seek to certain positions of the file for reading. We suggest
  using the standard C library functions for performing I/O, including fopen(),
  fread(), fseek(), and fclose().
- The size of physical memory is the same as the size of the virtual address space (65,536 bytes) so you do not need to be concerned about page replacements during a page fault.

### Input:

- addresses.txt, which contains 500 logical addresses ranging from 0 to 65535.
- BACKING\_STORE.bin

## Output file:

- The corresponding physical address: what your program translates the logical address to. (ex. 0xxxxxx\_address.txt, 0xxxxxx is your student ID) (20%)
- The signed byte value stored at the translated physical address. (ex. 0xxxxxx\_value.txt, 0xxxxxx is your student ID) (20%)

## Output on screen:

- 1. Page-faults (15%)
- Page-fault rate: The percentage of address references that resulted in page faults. (15%)
- 3. TLB hit times (15%)

4. TLB hit rate: The percentage of address references that were resolved in the TLB. (15%)
